Pred. No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.

This vector has insertion sites for foreign DNA fragments and is capable of autonomous replication. It can be used safely as they remain extrachromosomal and are very stable. They can be used to express homologous or heterologous proteins, which may include antigens for use in vaccines, nutritional, growth and clotting factors, antimicrobials, vitamins (especially vitamin B12), enzymes, hormones and drugs. The Propionibacterium host cells are used in the production of animal feeds, manufacture of foodstuffs like, sausages and cheese, where they may be used instead of or in addition to lactic acid bacteria and in the manufacture of vitamin B12. This sequence can also be used as a source of primers and probes.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Sequence

Mycobacterium

fortuitum

```
CC plasmid pAL 5000 origin of replication, ori which has been derived by PCR analysis. This sequence is used in a method which results in the CC formation of Mycobacterium recombinant vaccines from compositions that CC provide a continuous source of protein to an animal and stimulate CC cellular immunity. Such compositions are used to stimulate cellular CC immunity (by inducing Th-1 cells or cytotoxic T lymphocytes), CC particularly as vaccines (live or dead) for treating and preventing CC diseases caused by intracellular pathogens (bacteria, viruses, rickettsia CC or protozoa), and also cancer, autoimmune diseases, allergy and bovine CC administered by injection, orally and nasally. These compositions provide consistent and long-lasting immunity. Transformed cells used in the CC method are retained within macrophages, blocking the killing mechanism CC but producing protective immunogen which is processed and presented by the macrophage. Several immunogens may be included in the same vaccine and the Mycobacterium cells serve as adduvant.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Ş
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     닭
                                        This genomic DNA sequence contains is the Mycobacterium fortiutum CC plasmid pAL 5000 origin of replication, ori. This sequence is used in a CC method which results in the formation of Mycobacterium recombinant CC vaccines from compositions that provide a continuous source of protein to CC an animal and stimulate cellular immunity. Such compositions are used to Stimulate cellular immunity. Such compositions are used to CC stimulate cellular immunity for or dead) for treating and CC preventing diseases caused by intracellular pathogens (bacteria, viruses, CC rickettsia or protozoa), and also cancer, autoimmune diseases, allergy CC and bovine spongiform encephalitis, in humans or animals. The vaccines CC provide consistent and long-lasting immunity. Transformed cells used in CC provide consistent and long-lasting immunity. Transformed cells used in CC provide consistent and protective immunogen which is processed and CC presented by the macrophages. Several immunogens may be included in the CC came vaccine and the Murcharderium cells carve as additionart

                                                                                                                                                                                                                                                                             This sequence represents the plasmid pMV101. This plasmid was used in the construction of a series of vectors used to produce the recombinant Mycobacteria of the invention. The recombinant mycobacteria of the invention are transformed with DNA encoding a polypeptide which comprises a lipoprotein secretion signal sequence and an antigen (Ag) heterologous to the mycobacteria. The lipoprotein secretion signal causes the Ag to be produced as a lipoprotein. The mycobacteria may be used in the form of a live bacterial vaccines against Lyme disease, where the bacteria express a surface protein of Borrelia burgdorferi, the causative agent of Lyme disease.
                                                                                                                                              2852
                                                                                                                                                                                                                                                                                                                                                                                                                                                                Mycobacteria expressing secretion signal of lipoprotein and heterologous antigen, esp. outer surface protein A or B of Borrelia burgdorferi - are used in the form of a live bacterial vaccines

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Cassettes of all the components necessary for plasmid replication in E.coli and mycobacteria (E.rep and M.rep, respectively) and for selection of transformants (KanR) were constructed using the PCR technique. A multiple cloning site was synthesised. The cassettes were constructed to allow directional cloning and assembly into a plasmid where all transcription is unidirectional. Plasmid pMV206 was derived from plasmid pMV204 which was made up of all the cassettes. It was modified by the insertion of an Mull-NotI linker between the M.rep and E.rep cassettes to facilitate removal of

This sequence represents the plasmid pMV206. This plasmid was used in the construction of a series of vectors used to produce the recombinant Mycobacteria of the invention are transformed with DNA encoding a polypeptide which comprises a lipoprotein secretion signal apolypeptide which comprises a lipoprotein secretion signal
                                                                                                                                                                                                 Mycobacteria expressing secretion signal of lipoprotein and heterologous antigen, esp. outer surface protein A or B of Borr burgdorferi - are used in the form of a live bacterial vaccines
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  CDS
                      Lyme
                             sequence and an antigen (Ag) heterologous to the mycobacteria. The lipoprotein secretion signal causes the Ag to be produced as a lipoprotein. The mycobacteria may be used in the form of a live bacterial vaccines against Lyme disease, where the bacteria express a surface protein of Borrelia burgdorferi, the causative agent of

A multiple cloning site is inserted into pMH28 to give plasmid pMH29 (AAT28723), and a mutant firefly luciferase (EC-1.13.12.7) reporter gene is inserted to give plasmid pMY30-lux (AAT28278). This type of vector may be used in a new method for quantifying Mycobacterium infection in vivo. An animal is injected with e.g. Mycobacterium bovis BCG, etc., transfected by luminescence in tissues without lysis or cell concentration. The method may be used to determine the efficacy of
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Quantification of mycobacteria by luminescence - using treporter strains contg. a lux gene, permits the determn. efficacy of anti-mycobacterial and prophylactic compsns.

                                                                                                                                   밁
                                                                                                                                                                                                                                                                                                         This is the complete sequence of plasmid pMH29. This plasmid has to been constructed by inserting a multiple cloning site and an Escherichia coli TIT2 terminator sequence into plasmid pPA207SC, to based on plasmid pMY206 (AAT28281), to give plasmid pPA207SC) and insertion of a multiple cloning site to give pMH29. A mutant firefly lucliferase (EC-1.13.12.7) reporter gene is inserted to give plasmid pMY30-lux (AAT28278). This type of vector may be used in a new method for quantifying Mycobacterium infection in vivo. An animal is injected with e.g. Mycobacterium bovis BCG, etc., transfected with one of these vectors, and reporter gene expression is detected by luminescence in tissues without lysis or cell concentration. The method may be used to determine the efficacy of antibiotic, tuberculostatic and vaccine compositions.
